We have undertaken a series of eight 5-GHz VSOP observations of the relatively low-redshift (0.3) core-dominated superluminal quasar 1928+738. A range of proper motions has been detected and the observed kinematics are more consistent with a ballistic relativistic precessing jet model than a relativistic helical jet model.

Part of this research was performed at the Jet Propulsion Laboratory, California Institute of Technology, under contract to NASA. We gratefully acknowledge the VSOP Project, which is led by the Japanese Institute of Space and Astronautical Science in cooperation with many organizations and radio telescopes around the world.
